

How to upgrade a worker on OS X

There is no uninstall on OS X, so you simply stop the services and then install the newer Qube packages. No data is lost during the uninstall/re-install.

Stopping the Qube Worker

You will need to stop the Qube supervisor before you install over top of the older version. Since the supervisor is under `launchctl` control, so it can be stopped with this command:

```
sudo launchctl stop com.pipelinefx.worker
```

Installing the Qube Worker

The only condition is that the Qube-core is installed first. You can install all other Qube components in any order.

The most common order is

- install the Qube-core
- install the Qube worker
- install the QubeGUI
